### General Description

The MAX6314 low-power CMOS microprocessor (µP) supervisory circuit is designed to monitor power supplies in µP and digital systems. The MAX6314's RESET output is bidirectional, allowing it to be directly connected to µPs with bidirectional reset inputs, such as the 68HC11. It provides excellent circuit reliability and low cost by eliminating external components and adjustments. The MAX6314 also provides a debounced manual reset input.

This device performs a single function: it asserts a reset signal whenever the V<sub>CC</sub> supply voltage falls below a preset threshold or whenever manual reset is asserted. Reset remains asserted for an internally programmed interval (reset timeout period) after V<sub>CC</sub> has risen above the reset threshold or manual reset is deasserted.

The MAX6314 comes with factory-trimmed reset threshold voltages in 100mV increments from 2.5V to 5V. Preset timeout periods of 1ms, 20ms, 140ms, and 1120ms (minimum) are also available. The device comes in a SOT143 package.

For a µP supervisor with an open-drain reset pin, see the MAX6315 data sheet.

### \_Detailed Description

68HC11/Bidirectional-Compatible

The MAX6314 has a reset output consisting of a 4.7k $\Omega$  pull-up resistor in parallel with a P-channel transistor and an N-channel pull down (Figure 1), allowing this IC to directly interface with microprocessors (µPs) that have bidirectional reset pins (see the *Reset Output* section).

**µP** Reset Circuit

**Reset Output** 

A µP's reset input starts the µP in a known state. The MAX6314 asserts reset to prevent code-execution errors during power-up, power-down, or brownout conditions. RESET is guaranteed to be a logic low for V<sub>CC</sub> > 1V (see the *Electrical Characteristics*). Once V<sub>CC</sub> exceeds the reset threshold, the internal timer keeps reset asserted for the reset timeout period (t<sub>RP</sub>); after this interval RESET goes high. If a brownout condition occurs (monitored voltage dips below its programmed reset threshold), RESET goes low. Any time V<sub>CC</sub> dips below the reset threshold, the internal timer resets to zero and RESET goes low. The internal timer starts when V<sub>CC</sub> returns above the reset threshold, and RESET remains low for the reset timeout period.

The MAX6314's RESET output is designed to interface with  $\mu$ Ps that have bidirectional reset pins, such as the Motorola 68HC11. Like an open-drain output, the MAX6314 allows the  $\mu$ P or other devices to pull RESET low and assert a reset condition. However, unlike a standard open-drain output, it includes the commonly specified 4.7k $\Omega$  pull-up resistor with a P-channel active pull-up in parallel.

This configuration allows the MAX6314 to solve a problem associated with  $\mu$ Ps that have bidirectional reset pins in systems where several devices connect to RESET. These  $\mu$ Ps can often determine if a reset was asserted by an external device (i.e., the supervisor IC) or by the  $\mu$ P itself (due to a watchdog fault, clock error, or other source), and then jump to a vector appropriate for the source of the reset. However, if the  $\mu$ P does assert reset, it does not retain the information, but must determine the cause after the reset has occurred.

The following procedure describes how this is done with the Motorola 68HC11. In all cases of reset, the  $\mu P$  pulls  $\overline{\text{RESET}}$  low for about four E-clock cycles. It then releases  $\overline{\text{RESET}}$ , waits for two E-clock cycles, then checks  $\overline{\text{RESET}}$ 's state. If  $\overline{\text{RESET}}$  is still low, the  $\mu P$  concludes that the source of the reset was external and, when  $\overline{\text{RESET}}$  eventually reaches the high state, jumps to the normal reset vector. In this case, stored state information is erased and processing begins from

scratch. If, on the other hand,  $\overline{\text{RESET}}$  is high after the two E-clock cycle delay, the processor knows that it caused the reset itself and can jump to a different vector and use stored state information to determine what caused the reset.

The problem occurs with faster  $\mu$ Ps; two E-clock cycles is only 500ns at 4MHz. When there are several devices on the reset line, the input capacitance and stray capacitance can prevent RESET from reaching the logic-high state (0.8 x Vcc) in the allowed time if only a passive pull-up resistor is used. In this case, all resets will be interpreted as external. The  $\mu$ P is guaranteed to sink only 1.6mA, so the rise time cannot be much reduced by decreasing the recommended 4.7k $\Omega$  pull-up resistance.

The MAX6314 solves this problem by including a pullup transistor in parallel with the recommended  $4.7k\Omega$ resistor (Figure 1). The pull-up resistor holds the output high until RESET is forced low by the µP reset I/O, or by the MAX6314 itself. Once RESET goes below 0.5V, a comparator sets the transition edge flip-flop, indicating that the next transition for RESET will be low to high. As soon as  $\overline{\text{RESET}}$  is released, the 4.7k $\Omega$  resistor pulls RESET up toward V<sub>CC</sub>. When RESET rises above 0.5V, the active P-channel pull-up turns on for the 2µs duration of the one-shot. The parallel combination of the 4.7k $\Omega$  pull-up and the P-channel transistor onresistance quickly charges stray capacitance on the reset line, allowing RESET to transition low to high within the required two E-clock period, even with several devices on the reset line (Figure 2). Once the one-shot times out, the P-channel transistor turns off. This process occurs regardless of whether the reset was caused by Vcc dipping below the reset threshold, MR being asserted, or the  $\mu$ P or other device asserting RESET. Because the MAX6314 includes the standard 4.7k $\Omega$  pull-up resistor, no external pull-up resistor is required. To minimize current consumption, the internal pull-up resistor is disconnected whenever the MAX6314 asserts RESET.

#### Manual Reset Input

Many  $\mu$ P-based products require manual reset capability, allowing the operator, a test technician, or external logic circuitry to initiate a reset. A logic low on  $\overline{MR}$ asserts reset. Reset remains asserted while  $\overline{MR}$  is low, and for the reset active timeout period after  $\overline{MR}$  returns high. To minimize current consumption, the internal 4.7k $\Omega$  pull-up resistor on RESET is disconnected whenever RESET is asserted.

Figure 2. MAX6314 Supports Additional Devices on the Reset Bus

 $\overline{\text{MR}}$  has an internal 63k $\Omega$  pull-up resistor, so it can be left open if not used. Connect a normally open momentary switch from  $\overline{\text{MR}}$  to GND to create a manual reset function; external debounce circuitry is not required. If  $\overline{\text{MR}}$  is driven from long cables or if the device is used in a noisy environment, connecting a 0.1µF capacitor from  $\overline{\text{MR}}$  to ground provides additional noise immunity.

### Applications Information

#### **Negative-Going VCC Transients**

In addition to issuing a reset to the µP during power-up, power-down, and brownout conditions, these devices are relatively immune to short-duration negative-going transients (glitches). The Typical Operating Characteristics show the Maximum Transient Duration vs. Reset Threshold Overdrive, for which reset pulses are not generated. The graph was produced using negativegoing pulses, starting at VRST max and ending below the programmed reset threshold by the magnitude indicated (reset threshold overdrive). The graph shows the maximum pulse width that a negative-going Vcc transient may typically have without causing a reset pulse to be issued. As the amplitude of the transient increases (i.e., goes farther below the reset threshold), the maximum allowable pulse width decreases. A 0.1µF bypass capacitor mounted close to VCC provides additional transient immunity.

### Ensuring a Valid **RESET** Output Down to V<sub>CC</sub> = 0V

When V<sub>CC</sub> falls below 1V, RESET no longer sinks current—it becomes an open circuit. Therefore, high-impedance CMOS-logic inputs connected to RESET can drift to undetermined voltages. This presents no problem in most applications, since most  $\mu$ P and other circuitry is inoperative with V<sub>CC</sub> below 1V. However, in applications where RESET must be valid down to V<sub>CC</sub> = 0V, adding a pull-down resistor to RESET will cause any stray leakage currents to flow to ground, holding RESET low (Figure 3). R1's value is not critical; 100kΩ is large enough not to load RESET and small enough to pull RESET to ground.

†The MAX6314 is available in a SOT143 package, 0°C to +70°C temperature range.

\*\*The first two letters in the package top mark identify the part, while the remaining two letters are the lot tracking code.
\*\*\*Sample stocks generally held on the bolded products; also, the bolded products have lower minimum-order quantities. Contact

fur Sample stocks generally held on the bolded products; also, the bolded products have lower minimum-order quantities. Contact factory for details.

NOTE: All devices available in tape-and-reel only. Contact factory for availability.

†The MAX6314 is available in a SOT143 package, 0°C to +70°C temperature range.

the first two letters in the package top mark identify the part, while the remaining two letters are the lot tracking code.

ttt Sample stocks generally held on the bolded products; also, the bolded products have lower minimum-order quantities. Contact factory for details.

NOTE: All devices available in tape-and-reel only. Contact factory for availability.
